Vienna 13.04.20118

Patient: Michal H. Siemaszko (07/02/1979)

7th Ray Labs LTD

Request:

Femoral cutaneus lateral nerve injury after perosaonal attack?

Dysesthesia and numbness on the left lateral thigh.

Report: High resolution ultrasound was performed with a 18 MHz linear probe along the left thigh and inguinal area.

Ultrasound reveals a marked swelling of the femoral cutaneus lateral nerve at the level of he anterior superior iliac spine. The nerve swelling extends approximately for 15mm. The nerve runs in direct contact to the anterior iliac superior spine. There is no clear evidece of a nerve dissection. The cross sectional diameter oft he thickened nerve is 3 times above the normal value. The findings corrseponds to the previous MRI.

There are no abnormalities seen on Ultrasound along the inguinal ligament. Normal appearance of the lateral abdominal wall and the coresponding fascias. No enlarged inguinal lymphnodes.

After informed verbal consent of the patient an Ultrasound guided nerve block of the femoral cutaneus lateral nerve above the inguial ligament was performed, using 1 ml of local anestethetic. There was an immidiate numbness along the lateral thigh.

Conclusion:

Ultrasound reveals marked swelling of the femoral cutaneus lateral nerve at the left anterior superior iliac creast, suggesting iatrogenic nerve injury.

Sincerely

Gerd Bodner MD
